Abstract— Design patterns are widely used by software developers to build complex systems. Hence, they have been investigated by many researchers in recent decades. This leads to the emergence of various topics in the design patterns field. The objective of this paper is to present an overview of the research efforts on design patterns for those researchers who seek to enter this area. The main contributions are as follows: (a) identifying research topics in design patterns, (b) quantifying the research emphasis on each topic, and (c) describing the demographics of design patterns research. The last secondary study with similar goals in the design patterns field considers the Gang of Four design patterns only. However, the scope of the current study is all of the design patterns. Moreover, our review covers about six additional years and a larger number of publications and venues. In this systematic mapping study, a total of 2775 papers were identified as relevant, and 637 of them were included. According to the results, design patterns can be classified into six different research topics. As a consequence, it is concluded that Pattern Development, Pattern Mining, and Pattern Usage are the most active topics in the field of design patterns.

Design patterns, Systematic mapping study, Systematic review

1 Introduction

Software patterns are solutions to recurring software problems. These solutions are the result of the experiences of experts and can be used over and over again (Gama et al. 1995). Software patterns can be categorized into different classes according to the software development phase. Implementation patterns, testing patterns, analysis patterns, and design patterns (DPs) are some examples of these classes (Hamza 2004).

DPs, such as Gang of Four (GoF), and security DPs, are an active field of research in software engineering (Zhang and Budgen 2012; Zhang and Budgen 2013; Ampatzoglou et al. 2013; Riaz et al. 2015). In recent decades, many articles have been published on DPs topics which contribute to enriching the literature of the field. Hence, performing a comprehensive review and identifying the related themes and detecting trends and gaps in each of them is crucial. In other words, we need a reference guide so that we can conduct an effective investigation into each of the DPs topics and take significant steps to improve and enhance them.

To review the studies carried out in a broad area such as DPs, an advanced search method should be applied. This method should be able to cover this vast area and at the same time it must be reliable, repeatable, impartial, rigorous, and the results should be traceable. Evidence-based software engineering (Dyba et al. 2005) has provided this method. Two well-known methodologies that are provided by evidence-based software engineering are systematic literature review (SLR) and systematic mapping study (SMS) (Kitchenham et al. 2011; Petersen et al. 2015). There are some differences between SLR and SMS (Kitchenham et al. 2010; Kitchenham et al. 2011; Petersen et al. 2015). In general, methodologies for searching and extracting data in SMS and SLR are alike, but data analysis approaches are different, and research questions in SMS are more general than SLR (Kitchenham et al. 2011; Petersen et al. 2015). This is because of the differences between the aim of SMS and SLR. The purpose of SMS is identifying research trend and classifying topics that exist in a research area while SLR tries to find the primary studies and subsequently, extract data from them to answer a

specific research question (Kitchenham et al. 2011). When we intend to identify the scope of a topic and classify the studies that exist in this scope, we should use the mapping study method. Therefore, SMS can provide general information on one topic, and it can be done as a pre-review, before SLR.

In the field of DPs, some secondary studies have reviewed the literature. Among these studies, the only similar work to ours is a systematic mapping study that published in 2013 (Ampatzoglou et al. 2013). However, the scope of our study is all the DPs that exist in the literature, while Ampatzoglou et al. (2013) only considered GoF DPs. Moreover, our paper covers about six additional years, and a larger number of publications and venues. The results show that more than 30% of articles have been carried out from 2010 onwards. These differences make this work substantially different and worth investigation. In the Related Works section, the comparison between our work and other secondary studies in the field has been conducted in detail.

In this paper, an SMS on the literature of DPs has been carried out. This study contributes into providing a taxonomy of the research topics related to DPs as well as a breakdown of papers in each topic. Moreover, the researchers, countries, and publication venues that are active in research related to DPs are identified. Determining the taxonomy and demographics of a particular research topic can provide a useful starting point for other researchers. Therefore, using results that are extracted from this study, we want to present a reference guide for those researchers who seek to enter the DPs field and need to identify research trends and gaps.

The rest of the paper is organized as follows: related works is presented in Section 2. In Section 3, the systematic mapping technique is described. In Section 4, according to the research questions, the results of the systematic map are presented and subsequently in Section 5, the results are discussed. In Section 6, the threats to validity are discussed. Finally, in Section 7, conclusions and future works are presented. Note, we have prepared a document called DPs-SM (Design Patterns-Supplementary Material) to present the details of our SMS. This supplementary material is available on the web¹. Throughout this paper, whenever it is needed, we will refer to this document.

2 RELATED WORKS

Searching on the DPs field, we found a total of four secondary studies that use a systematic method to review the literature (see Table 1). Secondary study replications are valuable because, whenever new evidence is published after the completion of a secondary study, we should update it (Felizardo et al. 2016). In Table 2 we made a comparison between our paper and the other secondary studies in the field. As seen, among these studies, the only work with the same goals is the work of Ampatzoglou et al. (2013). According to Ampatzoglou et al. (2013), topics that exist in the field of DPs are identified and classified. The context of our study is all the DPs that exist in the literature, while Ampatzoglou et al. (2013) only considered GoF DPs. As illustrated in Table 2, our paper compared to other existing works, covers a larger number of publications and venues. In this paper, we present complete results and analysis to those researchers who seek to enter the field of DPs. Hence, as mentioned before, the result of our work can be used as a reference guide. It should be noted that the second goal in the work of Ampatzoglou et al. (2013) is evaluating the effectiveness of GoF DPs on software quality, while this purpose is not considered in our study.

TABLE 2: COMPARISON BETWEEN OUR WORK AND OTHER REVIEWS

3 RESEARCH METHOD

The review process used in this paper (see Fig. 1) is based on the updated guidelines for performing SMS which is presented by Petersen et al. (2015). In the work of Petersen et al. (2015) the authors conducted an SMS on SMSs in software engineering. Moreover, they presented a set of updated guidelines by considering the lessons learned through their mapping study and the guidelines presented in the work of Kitchenham (2004), Arksey and O'Malley (2005), Biolchini et al. (2005), Kitchenham and Charters (2007), Petersen et al. (2008), and Budgen et al. (2008). In the following sub-sections, the details of our method are discussed.

enter this field.

3.1 Planning the mapping study

In this phase, all the protocols and strategies which are needed for conducting a mapping study should be specified. Below, these protocols and strategies are described.

3.1.1 Specifying the scope and research questions (RQs)

The most important part of a systematic review is specifying the questions we intend to answer in the review process. These questions determine our goals, and the process of reviewing will be progressed by responding to these questions.

This study has been conducted from Jun 2015 until March 2016 and so we considered the studies that have been published until March 2016. The main goal is to identify and categorize research topics that exist in the field of DPs. So, the scope of our research is all the studies which have been conducted in this field. Furthermore, we want to present a reference guide for those who want to be active in the DPs area. Therefore, the research questions have been adjusted to achieve this goal. In the following, the research questions of our mapping study are described.

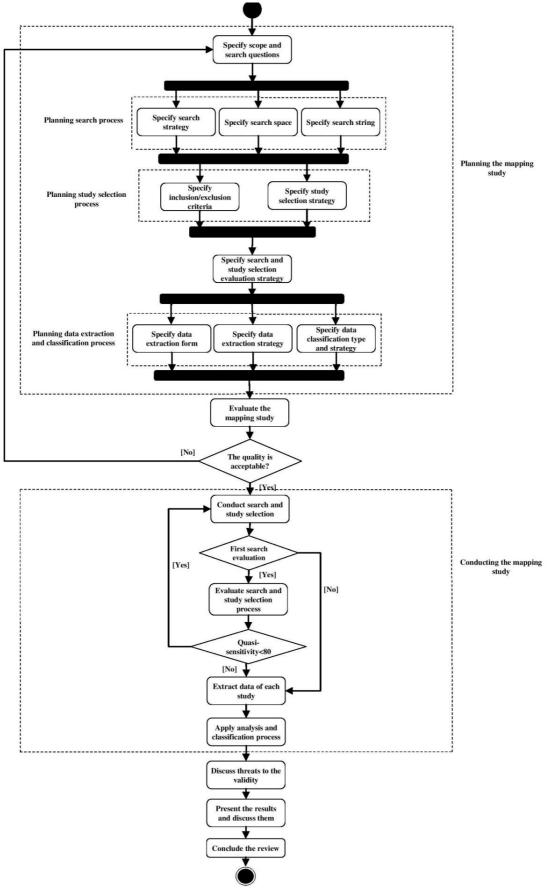

Fig. 1. The review process

RQ1: what are the core research topics in the field of DPs and how much emphasis has been given towards the field? Rational: by answering this question, we intend to meet the following goals: 1) finding out how attractive and important the research field of DPs has been for other scholars, how much work has been done in this area, and what has been the trend of the activity in this field, 2) identifying and classifying themes that exist in the DPs field (using the obtained taxonomy, researchers can explore existing topics and sub-topics in this field), and 3) identifying the trends and gaps in each topic.

RQ2: which countries, researchers, and venues have been more active in the area of DPs? Rational: by answering this question a useful starting point will be provided for other researchers who are interested in this field.

3.1.2 Planning the search process

After specifying scope and research questions, we defined all the protocols and decisions which are relevant to conducting the search process including specifying search strategy, search space, and search string. The descriptions are given below.

3.1.2.1 Specifying the search strategy

For conducting the search, at first, the search strategy should be specified. In this work, we used manual search and backward snowballing (Jalali and Wohlin 2012) for the identification of relevant studies. We should note some points: 1) before starting the process, the set of search spaces (which is, at first, an empty set and will gradually be completed as the search process progresses) should be defined. The members of this set are pairs of "search space" and "related timestamp". 2) The activity of identifying the related journals, conferences or workshops of newly included papers is not necessary to be conducted after the manual search. Therefore, we have defined a flag named S_Flag which is set to one in the backward snowballing step and is set to zero in the second step of the process.

Fig. 2 shows all the steps in our search strategy. This strategy consists of five steps. The description of each step is as follows:

Step 1: at the first step, the initial set of papers should be selected. As described in Section 3.3.1, we reached this set by conducting an informal search.

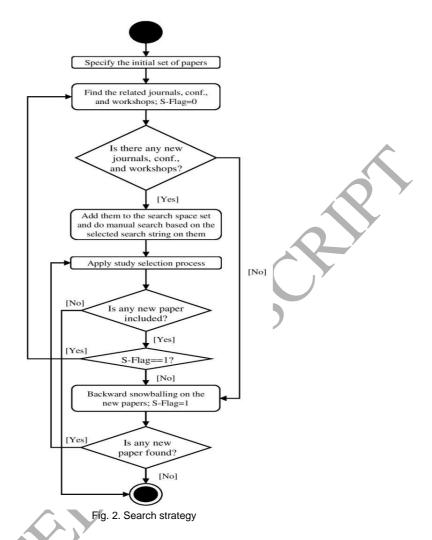

Step 2: in this step, the related journal, conference or workshop of each included paper should be extracted and compared with members of the search space set. If there is any new journal, conference or workshop, the third step should be executed; otherwise, the fifth step of the search process will follow.

Step 3: the extracted journals, conferences or workshops with the related timestamp (current time) should be added to the search space set, and a manual search on them should be done based on the search string (in order to find more relevant papers).

Step 4: in this step, the study selection process (see Section 3.1.3.2) should be applied. Depending on whether a paper is included or not, and whether the included paper is the result of the backward snowballing step or not, we should end the process or move to step 2, or 5.

Step 5: at the last step, the backward snowballing, which is finding the relevant papers by investigating references of included papers, should be conducted (on those papers which have not been snowballed before). If any new paper is found, the search process continues from step 4. Otherwise, it ends.

Note: our search process has been done from Jun 2015 until March 2016. If during this time interval each search space had been examined only once, in some search spaces new articles which were published after the first manual search would have been ignored. This is a threat to the completeness of the included papers set. To remove this threat, in the third step of the search strategy, a timestamp for each included search space should be inserted. After finishing the search process, the timestamps will be checked. If there exists a case which is greater than or equal to six months passed, the related search space should be investigated again (since the timestamp, until the current time).

3.1.2.2 Specifying the search space

According to the search strategy, at the starting point of the search process, the search space set (a set of journals, conferences, and workshops) is empty. After conducting an informal search, some search spaces will be added to the search space set (see Section 3.3.1). This set will be completed with the progress of the search process. In Appendix \rightarrow Table C and D, the final search space set and related information are shown. More information can be found in DPs-SM \rightarrow Chapter 1 \rightarrow Tables 1-3 to 1-7.

3.1.2.3 Specifying the search string

According to the context of our mapping study which is software DPs, we chose "design pattern" as the search string and applied it in the title, abstract, and full text of the papers.

3.1.3 Planning the study selection process

For the study selection, two important tasks should be done. First, inclusion/exclusion criteria should be specified and second, the strategy of study selection should be defined

3.1.3.1 Specifying the inclusion/exclusion criteria

For the identification of those primary studies that can answer our research questions, we should define two categories of criteria (called study selection criteria). The first category is the inclusion criteria (see Table 3). In the current mapping study, one inclusion criterion is defined. The second category is the exclusion criteria (see Table 4) which exclude those articles that are not desired. If an article has at least one of the exclusion criteria, it will be excluded. In other words, a paper will be included if the inclusion criterion is met and none of the

exclusion criteria is satisfied. Note, according to Table 4, the secondary studies should not be included. However, we considered these studies just to compare them with our study.

Here, the thresholds used for the exclusion criteria are obtained empirically. For selecting the appropriate threshold values, we considered two issues: 1) slight changes in these values should not make many changes in the number of excluded/included papers and 2) threshold values should be selected in such a way that applying them does not exclude a lot of highly cited papers.

TABLE 3: INCLUSION CRITERIA

I	No.	Description
ſ	1	The focus of the paper is on the software DPs

TABLE 4: EXCLUSION CRITERIA

No.	Description
1	The study relates to other patterns, not DPs, e.g. architectural patterns
2	If the study is a journal paper and the related journal is not indexed in the list of ISI journals
3	If the study is a journal paper and for the related journal ((SJR is not available) or (SJR < 0.4)
4	If the study is a conference paper and for the related conference (Qualis < B4) and (ERA < B) and (h5 - index < 10) and (Period < 10)
5	The study is not a paper, e.g. it is a gray literature, conference cover, poster, etc.
6	The study is not a primary study, e.g. it is a survey, literature review, etc.

3.1.3.2 Specifying the study selection strategy

To include relevant papers, we specified the study selection strategy which is shown in Fig. 3. This strategy consists of two evaluation stages. At the first stage, the paper should be evaluated by title, keywords, information of the publication venue, and abstract. At the second stage, the paper should be evaluated by full-text. After each stage, a decision should be made. Note that in each evaluation stage both inclusion and exclusion criteria should be considered. In each stage, meaningful terms and keywords of included papers should be highlighted. This is useful for the classification of these papers.

Each paper should be evaluated by two reviewers (first and third author) separately, and they should check their results with each other at the end. In Table 5, the decisions rules are defined. According to this table, nine states may occur. In the case of "uncertain" condition, one other reviewer (second author) should judge between them. Note, if there is still a disagreement, even after the judgment, the paper should be included.

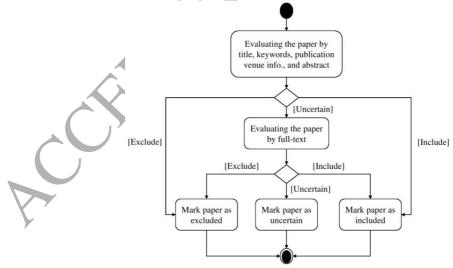

Fig. 3. Study selection strategy

TABLE 5: DECISIONS RULES

STATE	TE INCLUDE EXCLUDE		UNCERTAIN	
Include	Include	Uncertain	Include	
Exclude	Uncertain	Exclude	Exclude	
Uncertain	Include	Exclude	Uncertain	

3.1.4 Specifying the search and the study selection evaluation strategy

Evaluating the search strategy can be done in two ways: 1) subjective evaluation (using the expert review), 2) objective evaluation (using the quantitative criteria). The subjective evaluation could be biased in terms of the expert opinion. Therefore, in this study, we used a quantitative criterion (quasi-sensitivity) to evaluate the search and the study selection process. "Sensitivity" is the proportion of the included studies for a given topic and can be calculated by the following equation:

Sensitivity = (Number of included studies / Number of studies in a full set of studies)*100 (1)

However, obtaining a full set of primary studies (gold standard) is almost impossible. So, we used the Quasi-Gold Standard (QGS) to obtain the sensitivity (Zhang et al. 2011). QGS is a set of known studies from key sources, which are recognized by the community in the subject. In this mapping study, to establish the QGS, we got help from eight members of the software quality lab².

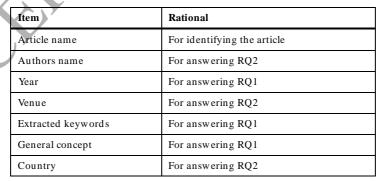

The lab members identify some key researchers in the field of DPs, during the informal search from sources such as c2.wiki website, books, courses, and editor-in-chief of journals or conferences. Afterward, referring to web-pages of the key researchers and gathering their related papers (after applying the inclusion and exclusion criteria), the QGS was generated. In Appendix \rightarrow Table E and Table F, the authors, web-pages, and extracted papers are shown. More information can be found in DPs-SM \rightarrow Chapter $2 \rightarrow$ Table 2-8.

After establishing the QGS, and calculating the quasi-sensitivity, we should compare the obtained value with a threshold. If the quasi-sensitivity was less than the predefined threshold, we should conduct the search and study selection again on the newly found papers in QGS. According to Zhang et al. (2011), it is suggested that an acceptable threshold should be between 70% and 80%. In this study, we chose 80% as the threshold.

3.1.5 Planning the data extraction and the classification process

To extract data from the included studies, we prepared data extraction forms. In Table 6, the items of these forms and the reason for considering each item is shown. Data extraction process was done in two stages. At first, we divided included papers into two sets, and the data extraction operation was performed by two reviewers (for each set, one reviewer). At the second stage, the results of each reviewer were checked and traced back by a third reviewer. If the third researcher found any inconsistencies, the issue was raised in the group meetings to reach an agreement.

TABLE 6: ITEMS OF DATA EXTRACTION FORM

² http://sqlab.um.ac.ir/index.php?lang=en

According to Petersen et al. (2015) the differences between general classification and topic dependent classification are distinguished. In this study, for the general classification, applied facets are the venue, year, and country. To achieve the research tree of the DPs field and identifying research topics, we applied keyword clustering which is a common method for topic dependent classification (see Section 3.3.4).

3.2 Evaluating the mapping study

To evaluate our mapping study, we used the evaluation rubrics presented by Petersen et al. (2015). In Table 7, the rubrics, the related actions which have been done in this study, and the evaluation degree are shown. According to the related actions, we assigned a degree (no description, minimal, partial, and full) to each rubric based on the requirements defined by Petersen et al. (2015). In the last column of Table 7, for each rubric, the ratio of the number of mapping studies with the same evaluation degree, to the total number of mapping studies investigated by Petersen et al. (2015) is shown. The evaluation results demonstrate that this mapping study has been conducted on the acceptable level of quality, compared with other studies investigated by Petersen et al. (2015). Note, if the quality was not acceptable, the planning phase should be revised (according to each rubric).

Evaluation degree of the mapping studies Rubric Actions **Evaluation degree** investigated by Petersen et al. (2015) Need of the study, motivations, Specifying scope and research questions objectives and research 100% partial questions are defined About 40% no description, Manual search and backward Specifying search strategy minimalabout 23% minimal, about snowballing are used 19% full The quasi-gold standard is used to evaluate the search and About 44% no description, Evaluating search and study selection selection process; an additional partial about 42% minimal, about person is added to judge when process 14% partial disagreement occurs, and decision rules are taken An additional person is added to trace back and check extracted data, two About 10% no description, Data extraction and classification classification schemes (general minimal about 61% minimal, about classification and topic 29% partial dependent classification) were used The threats to validity are About 14% no description, full Threats to validity about 86% full discussed

TABLE 7: EVALUATION RUBRICS

3.3 Conducting the mapping study

After specifying the protocols and strategies of the mapping process, they should be applied in the conducting phase. The details are explained below.

3.3.1 Conducting the search and the study selection process

As mentioned before, to start the search process, the initial set of papers should be determined. After obtaining the initial set, the rest of the search process was performed according to the search and the selection strategies. The second author identified the initial set by performing the following steps. In the first step, an informal search was carried out to find the secondary studies which had been conducted in the field of DPs. The informal search was undertaken using 'Google Scholar' and the search term 'design pattern' combined with terms such as 'review', 'systematic review', 'systematic mapping study', 'systematic literature review', or 'survey'. Then, according to the study selection criteria (exclusion criteria (6)), some secondary studies were

selected (see Appendix →Table A). In the next step, by investigating the primary studies which had been considered by the secondary studies obtained from the previous step, 303 papers were identified as the candidate members of the initial set. Afterwards, by applying the selection process on the candidate members, 101 papers remained and formed the final initial set (see Appendix →Table B).

In general, by conducting the search process, 36 journals and 53 conferences (or workshops) were identified as the desired search spaces and a total of 1484 conference papers and 965 journal papers were identified as relevant papers. After applying the study selection strategy, 155 journal papers and 368 conference or workshop papers remained and were included. Note, in Appendix → Tables C, and D, the number of the relevant papers (before applying study selection process) and the number of the included papers (after applying study selection process) of each search space are shown.

3.3.2 Evaluating the search and the study selection process

In our study, we achieved the sensitivity of 79%. So, we conducted the search and study selection again on the newly found papers in QGS. In the QGS, there were 23 new papers which we did not include (because the venues of them were not considered in our search). We took these papers as the initial set and conducted the search strategy on them. Finally, 3 new journals and 16 new conferences were added to the search space set and subsequently 93 conference papers and 21 journal papers were added to our included set. In Appendix \rightarrow Table F, data extracted for the evaluation phase are shown. More details of this phase are presented in DPs-SM \rightarrow Chapter 2 \rightarrow Table 2-8.

3.3.3 Data extraction

At this stage, according to the data extraction forms, useful data were extracted. As we mentioned earlier, the extraction has been conducted by two reviewers and checked by the third one. In the DPs-SM \rightarrow Chapter 1 \rightarrow Tables 1-8 to 1-11, the filled forms are available.

3.3.4 Analysis and classification

The data extracted in the previous step were analyzed and tabulated according to the related research question(s). For example, to answer the RQ1, the papers were tabulated based on the year and counted afterward. In Section 4, the results of this stage are visually illustrated.

As mentioned before, the main goal of an SMS is classifying the primary studies that have been included in the intended subject. In the current systematic mapping, using keyword clustering we classified those primary studies that have been included in the field of DPs. We applied the keyword clustering, as mentioned by Febrero et al. (2014) and Noyons et al. (2000), on the meaningful terms (keywords) which was extracted at the first step from the title, author's keywords, and abstract of the primary studies. These meaningful terms should reflect the purpose or contribution of the paper. Here, at first, about 1135 keywords and phrases were extracted as the meaningful terms. Then, we characterized the most frequent terms. We identified about 30 frequent terms which were repeated more than 10 times (see DPs-SM →Chapter 1 →Tables 1-11), and clustered them into 5 groups on the basis of their similar cognitive orientation. These groups were obtained by a hierarchical clustering algorithm with complete linkage on the keyword normalized co-occurrence matrix (Noyons et al. 2000). In the keyword co-occurrence matrix both the rows and the columns represent the keywords and each cell shows the number of times that the keywords corresponding to the row and the column of that cell appear together in a study (see DPs-SM →Chapter 1 →Tables 1-12). Then, based on the cosine index (see eq. (2)), we normalized the co-occurrence matrix.

$$sim(i,j) = \frac{\sum_{k=1}^{n} X_{ik} X_{kj}}{\sqrt{((\sum_{k=1}^{n} X_{ik}^{2})(\sum_{k=1}^{n} X_{kj}^{2}))}}.$$
 (2)

Where X_{ij} is the number of co-occurrences of keyword i with keyword j.

In the recalculated matrix, the similarity of keywords will be based on the cognitive orientation of two keywords in relation to all other keywords. Note, we determine the number of clusters empirically. We chose this number in such a way that the papers can be divided into balanced clusters (as much as possible). In the last step, a proper name for each cluster should be selected according to the most frequent keywords and the whole concept of the cluster (see Table 8).

By applying the above-mentioned method on the frequent keywords in the field of DPs, we identified the following research topics: 1- Pattern Development, 2- Pattern Usage, 3- Pattern Mining, 4- Quality Evaluation, and 5- Pattern Specification.

After specifying the main category, we specialized and divided these topics into some possible sub-topics. To do so, based on the authors' field experience, we considered a suitable discriminator for each topic. Then, each topic was divided based on the corresponding discriminator, and a complete classification was achieved. The details of each category and the related sub-categories are given in Section 4.

Finally, we mapped each paper to its corresponding category based on its extracted keywords. If in a particular paper any of the frequent keywords existed, the paper was mapped to the category to which the keywords belong. Otherwise, we considered the frequent keywords and found semantically similar keywords in the paper. Then, based on these similar keywords, we mapped the paper to its corresponding category. If a paper was found which could not be mapped to any of the categories, we mapped it to the Miscellaneous Issues category. Note that in some cases, according to the extracted keywords, a paper may belong to more than one category. These papers were judged, and the most related category was chosen.

Category	Keywords	Concept
Pattern Development	Name of a new pattern (e.g. OCO design pattern), Categorization/ Classification/ Cataloging, (Design) Pattern language(s), Pattern(s) Composition(s)/ Composition, (Software) Evolution	Any development in the field of DPs research
Pattern Usage	Using, (DP(s)) Applying/ Application	Designing domain-specific applications with patterns, presenting pattern-based methods, or Incorporating and applying DPs in the software design/code
Pattern Mining	Detection, Recovery, Identification, Recognition	Finding instances of the pattern in the system code/ design.
Quality Evaluation	Quality, (Quality) Evaluation/ Measurement/ Assessment, Quality attributes (such as maintenance and reusability), (Evaluation by) Metric(s), (Evaluation by) Empirical/ Experimental (Methods)	Assessing the quality of the patterns or assessing the impact of applying DPs on the quality of the system
Pattern Specification	(Pattern) Specification/ Specifying, Formalism/ Formal (method(s)), Visualization/ Visual, Modeling Languages (such as UML), Verification/ Verifying	Using different methods and notations for describing the patterns

TABLE 8: KEYWORDS AND RELATED CONCEPTS OF CATEGORIES

4 RESULTS

In this section, the results are presented with respect to the research questions specified in Section 3.1.1. First, in Section 4.1 research topics and sub-topics that have been identified in this review, and frequency of papers are presented. Next, in Section 4.2, active countries, researchers, and venues in the field of DPs are provided.

4.1 Identifying the research topics and frequency of papers (RQ1)

In the late 1960s and early 70s, Christopher Alexander introduced the patterns concept in architecture (Najari et al. 2016). In 1993, it was suggested to forge a marriage of objects and patterns. Then, in 1995, the idea of patterns was adopted in object-oriented software development (c2.wiki 2016). In the same year, Gamma's book was released (Gamma et al. 1995). According to scholars, Gamma's book is the most effective activity to pick up the topic of DPs (Ampatzoglou et al. 2015). In Gamma's book, with the aim of solving some commonly-recurring design problems, 23 DPs are cataloged (Gamma et al. 1995).

According to the above-mentioned explanations, we considered the time interval starting from 1995. Fig. 4 illustrates the number of papers on DPs during the last two decades (from 1995 to 2015). Note, since we did not consider the full year of 2016 in our review, the number of the publications in 2016 is not presented in this figure (from the beginning of 2016 to March, only two papers were included). As seen in Fig. 4, from the total number of 637 papers including archival journal and conference articles, about 62% of articles (393 papers) have been published in the recent decade. Therefore, it can be concluded that similar to some old topics such as

software architectural decisions (Tofan et al. 2015) or trending topics such as technical debt (Li et al. 2015), DPs research is a hot topic and the attention to the subject is increasing.

Fig. 4. Frequency of publications per year

For identifying the research topics, as mentioned in Section 3.3.4, we used the keyword clustering method. Extracting the keywords and meaningful terms of the primary studies and presenting the most repeated of them is a common and good practice in an SMS. In this mapping study, about 1135 keywords and phrases were extracted. Fig. 5, shows 30 most frequent of these keywords and phrases. As seen, "Security Patterns" (representative of words such as (Software) Security pattern(s), Security design pattern(s), or Security), "Object Orientation" (representative of words such as (Object Orientation, or OO), and "Pattern Detection" (representative of words such as ((Design) pattern(s)) Detection, or Detecting) are the most frequent phrases in the literature of DPs.

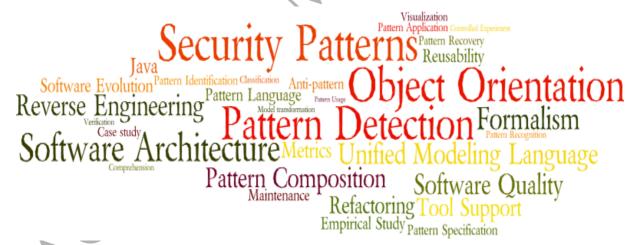

Fig. 5. Common keywords and phrases in DPs field, drawn with http://www.wordle.net/

By applying the keyword clustering algorithm (see section 3.3.4), we obtained a classification which is shown in Fig. 6. The main categories of this classification are Pattern Development, Pattern Usage, Pattern Mining, Quality Evaluation, Pattern Specification, and Miscellaneous Issues. In Table 8, the extracted keywords that were useful for classification is shown. Below, the details of each category (topic) and sub-category (sub-topic) are given.

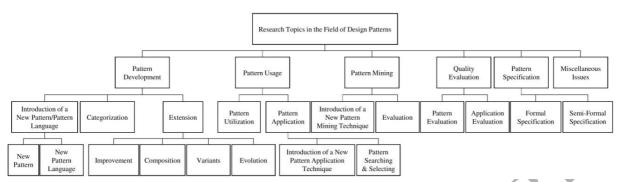

Fig. 6. DPs research tree

The Pattern Development category

Pattern Development category indicates any development in the field of DPs research, including:

- Introducing a new pattern or new pattern language. A pattern language is a collection of interrelated DPs that are carefully organized to characterize a design methodology. Note that a pattern language is more than only a catalog of patterns and the structure of the pattern language guides the user to design complex systems using the patterns (Massingill et al. 2001; Zhao et al. 2008; Pauwels et al. 2010; Hafiz 2013). "New pattern language" and "New pattern" sub-categories, refer to these definitions.
- Discussing pattern variants, pattern evolution, composing patterns or improving a specific pattern. Variability in patterns refers to the changes (in structure or behavior) that can occur inside of a DP when it is implemented while keeping the main parts of the pattern (Kim and Shen 2008). DPs embed some special ways for future changes. Evolution in DPs implies future changes in patterns during the evolution of the software (Schanz and Izurieta 2010; Griffith and Izurieta 2014; Rossi and Russo 2014). Pattern composition means assigning multiple elements of the pattern into overlapping sets of system classes (Dong 2002; Dong et al. 2007; Cacho et al. 2014). Pattern improvement indicates introducing an alternative for an existing pattern with the aim of overcoming its limitations (Lyon and Castellanos 2007; Fortuin 2010; Pati and Hill 2012). To cover these issues, the "Extension" sub-category which is divided into "Variants", "Composition", "Improvement", and "Evolution" is defined.
- Categorizing existing DPs in various fields such as mobile applications (Nilsson 2009), security (Hafiz et al. 2007; Van-Hilst 2009), model transformation (Lano and Kolahdouz-Rahimi 2014), and ontology (Tsai et al. 2013). These issues are listed under the "Categorization" sub-category.

In Table 9, the most frequent keywords in "Pattern Development category" are shown. Term frequency for each keyword refers to the number of papers in which the keyword existed. As shown, the main keywords of the Pattern Development category are "(Software) Security pattern(s)/ Security design pattern(s)/ Security", "Pattern(s) Composition(s)/ Composition", "(Software) Architecture", "(Software) Evolution", "(Design) Pattern language(s)", "Object Orientation/ OO", and "Categorization/ Classification/ Cataloging". As mentioned, one of the sub-topics in this class is introducing a new pattern or a new pattern language. High repetition of the phrase "Security pattern(s)" indicates that security is one of the most interesting topics in which researchers tend to introduce new pattern or pattern language.

TABLE 9: THE MOST FREQUENT KEYWORDS IN "PATTERN DEVELOPMENT" CATEGORY

Keywords	Frequency
(Software) Security pattern(s)/ Security design pattern(s)/ Security	31
Pattern(s) Composition(s)/ Composition	27
(Software) Architecture	23
(Software) Evolution	19
(Design) Pattern language(s)	16
Object Orientation/ OO	15
Categorization/ Classification/ Cataloging	12

The Pattern Specification category

The Pattern Specification category includes those papers which use different methods and notations for representing the patterns. There are various specification schemes which are proposed to complement the natural language description of the patterns. These schemes can be classified into two main groups:

- Formal specification schemes: specification of a program's properties by mathematically based techniques (formal languages) which are well understood. A formal language for DPs is a language with a precisely defined vocabulary, syntax, and semantics which aims to reduce the ambiguities by rigorously reasoning about the structural and behavioral aspects of patterns (Kim and Carrington 2009; Zhu and Bayley 2013).
- Semi-Formal specification schemes: specifying DPs with semi-formal languages. A semi-formal language is a language with a precisely defined vocabulary and syntax, but without a precisely defined semantics (Dong et al. 2007; Porras and Guéhéneuc 2010).

"Formalism/ Formal (method(s))", "Unified Modeling Language (UML)", and "(Pattern) Specification/ Specifying", are the most repeated keywords in the Pattern Specification group (Table 10). This means that formal methods have been greatly considered by researchers in the field of specifying patterns and UML is the most attractive semi-formal model for visualizing DPs.

Keywords	Frequency
Formalism/ Formal (method(s))	32
Unified Modeling Language (UML)	22
(Pattern) Specification/ Specifying	17
Object Orientation/ OO	9
Verification/ Verifying	8
Visualization/ Visual	6

TABLE 10: THE MOST FREQUENT KEYWORDS IN "PATTERN SPECIFICATION" CATEGORY

The Pattern Usage category

This category consists of the papers with the contribution of employing patterns in the software development process. This topic can be classified into two main classes:

- Pattern Utilization: presenting pattern-based methods or designing domain-specific applications with DPs.
 DPs can be used in various fields and applications such as security (Fernandez et al. 2013; Uzunov et al. 2015), CAD models (Bai et al. 2016), and object-oriented programming (Kienzle and Romanovsky 2002).
 Using DPs can help to standardize the design concepts, capture design experiences, reuse elegant and efficient solutions, and improve documentation and maintenance.
 - Pattern Application: incorporating and applying DPs in the software design/code. Papers in the "Introduction" subcategory try to assist the process of applying patterns using manual or automatic methods. However, the "Pattern Searching & Selecting" subcategory deals with the problem of finding a suitable DP to apply and solve a particular problem (Aliaksandr Birukou 2010). Searching patterns imply obtaining information about existing patterns in the literature and online repositories, and selecting patterns means choosing an appropriate pattern in the list which is obtained at the stage of searching patterns or is pre-defined (Aliaksandr Birukou 2010; Sarun and Weenawadee 2007; Zdun 2007; Hasheminejad and Jalili 2012).

According to Table 11, "(software) Security pattern(s)/ security design pattern(s)", "(Software) Architecture", "Object Orientation/ OO" are the most common keywords in this field. This shows that the security and the software architecture are areas in which DPs are most widely used.

TABLE 11: THE MOST FREQUENT KEYWORDS IN "PATTERN USAGE" CATEGORY

The Quality Evaluation category

Whenever a designer or a developer employs a pattern, one of the most important concerns is the quality of the pattern and the effect of the pattern on the system after applying. The Quality Evaluation category includes those papers with the purpose of quality evaluation in the field of DPs. This topic can be classified into two main classes:

- Pattern evaluation: assessing the quality of the patterns (Halkidis et al. 2006; Ampatzoglou et al. 2011; Elish and Mohammed 2015).
- Application evaluation: assessing the impact of applying DPs on the quality of the software system (Jaafar et al. 2014; Scanniello et al. 2015; Ampatzoglou et al. 2015).

Assessing the pattern quality is a challenging task. Similarly, evaluating the effect of patterns on quality attributes is tough. As the current state of the art stands, evaluation of DPs has been performed through two main activities: 1) computing code metrics (quantitative methods), 2) using expert opinion (empirical methods) (Ampatzoglou et al. 2013). As expected, concerning Table 12, it is observed that "(Software) Quality/Qualitative analysis", "Metric(s)", "Empirical (study(s))", and "(Controlled) Experiment" are frequent keywords in the studies that evaluate the quality of the patterns or the impact of applying them on system quality.

TABLE 12: THE	MOST FREQUENT KEYWORDS IN "QUALIT	Y EVALUATION" CATEGORY
	Keywords	Frequency
	(C - f) O l'+/ O l'+-+' l'-	22

Keywords	Frequency
(Software) Quality/ Qualitative analysis	33
Metric(s)	13
Empirical (study(s))	13
Object Orientation/ OO	12
(Controlled) Experiment	9

The Pattern Mining category

Finding instances of the pattern in the systems source code or design is the purpose of the papers which were included in this category. Detection of DP motifs can provide a better glimpse to recognize the original design decisions. Hence, it is important in the process of refactoring, reengineering, and maintenance. Furthermore, it can be helpful for software quality measurement, program understanding, and improving software documentation. However, this is not a straightforward task. Papers which discuss the Pattern Mining field can be classified into two main groups:

- Introduction: Introducing a new method for the detection of DPs (Yu et al. 2015; Zanoni et al. 2015; Wen-Jin et al. 2015).
- Evaluation: Evaluating mining techniques for DPs (Bouassida et al. 2013; Ujhelyi et al. 2015).

Table 13 elucidates that the keywords used in the published papers on mining DPs are mostly "((Design) pattern(s)) Detection/ Detecting", "Reverse engineering/Re-engineering", "((Design) pattern(s)) Recovery", and "((Design) pattern(s)) Identification/ Identifying". "Detection", "Recovery", and "Identification" are synonymous with the word "Mining". DP Mining is a significant part of the reverse engineering process that can aid program comprehension. Hence, the "Reverse engineering" keyword is repeated commonly in the Pattern Mining studies.

TABLE 13: THE MOST FREQUENT KEYWORDS IN "PATTERN MINING" CATEGORY

Keywords	Frequency
((Design) pattern(s)) Detection/ Detecting	64
Reverse engineering/ Re-engineering	36
((Design) pattern(s)) Recovery	19
((Design) pattern(s)) Identification/ Identifying	18
Tool (Support)	14
Object Orientation/ OO	12
((Design) pattern(s)) Recognition	12
Antipattern	10

The Miscellaneous Issues category

This class includes studies that cannot be classified into any other previous topics (Ampatzoglou et al. 2013; Gaitani et al. 2015; Aljasser 2016). These studies typically discuss issues such as, refactoring, code smells & antipatterns, and implementing patterns in a special language. Miscellaneous Issues cannot be regarded as individual topics because they reflect enormous heterogeneity, and they lack enough maturity.

Table 14 demonstrates that the most frequent keyword in the Miscellaneous Issues is "Refactoring". Refactoring is the process of restructuring a software system in such a way that it improves the internal structure of the system without altering the external behavior of the code. Designs can be improved with patterns by applying sequences of design transformations, known as refactoring (Kerievsky 2005).

TABLE 14: THE MOST FREQUENT KEYWORDS IN "MISCELLANEOUS ISSUES" CATEGORY

Keywords	Frequency
Refactoring	20
Object Orientation/ OO	17

Reuse/ Reusability	8

Fig. 7 depicts the percentage of publications for the diverse topics of DPs. As observed, most of the scholars have focused on Pattern Development, Pattern Mining, and Pattern Usage, while less consideration is given to Pattern Specification, and Quality Evaluation categories.

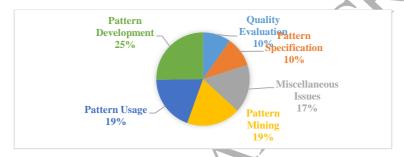

Fig. 7. Percentage of publications per topic

Table 15 has been presented to show the number of publications in different fields of DPs (as discussed in Fig. 7) for different years. It is observed that, in general, three branches of DPs including Pattern Development, Pattern Mining, and Pattern Usage had the highest growth in the number of publications during the recent years. Moreover, in this table, we have highlighted the most frequent categories for each year.

4.2 Identification of active countries, researchers, and venues

The results obtained from the data analysis for this research question are shown in the following figures and tables.

The geographical distribution of publications (GDP) for a particular topic is an indicator of the productivity of the research topic of individual countries and has become a field of interest. In Fig. 8, the geographical distribution of publications in the field of DPs from 1995 to March 2016 is shown. As seen, USA has the highest share (23%) from the total number of publications. Canada, Germany, and Italy stand in the next ranks after the USA. According to our inspection of the country rankings provided by SCImago Country Rank in 2016 (SCImago 2016), USA, China, UK, Germany, Japan, France, Canada, and Italy are the most active countries in the number of scientific articles respectively. Similarly, USA, Canada, Germany, Italy, UK, China, and France are among the countries with the highest number of publications in the field of DPs. However, as shown in Fig. 8, there are some countries such as Greece and Brazil which their activity level in the DPs field are beyond what was expected. Considering the affiliation and the nationality of communities, projects, pioneers, and renowned researchers in the field of DPs research which illustrated in DPs-SM →Chapter 2 →Tables 2-1 to 2-2 and Table 2-7 and DPs-SM →Chapter 3 →Tables 3-2, it can be concluded that there exists a strong relationship between them and the number of papers produced in each country.

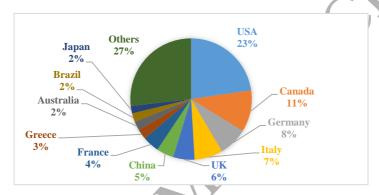

Fig. 8. Geographical distribution of publications

Identification of key scholars in a field of research can help those researchers who want to enter the research field. As mentioned before, from each included paper, we extracted the name of the authors. In total, 1078 authors were identified in the DPs field. In Table 16, ten most active researchers in the DPs field with their number of publications are presented. Moreover, in this table, we have highlighted the most important researcher per domain.

	Quality	Pattern	Miscellaneous	Pattern	Pattern	Pattern	Total

TABLE 16: TEN MOST ACTIVE RESEARCHERS IN DPS FIELD

Table 17 demonstrates the most popular conferences in the field of DPs. The International Conference on Pattern Languages of Programs (PLoP) has published the largest number of conference papers related to DPs. European Conference on Object-Oriented Programming (ECOOP), Asia-Pacific Software Engineering Conference (APSEC), International Conference on Software Engineering (ICSE), and OOPSLA stand in the next ranks after the PLoP.

Table 18 represents the distribution of the publications in DPs topics over the 13 most active conferences in the field. For example, this table shows that in the pattern development category, 28.15 percent of the conference papers are published in the PLoP conference. In this table, we have highlighted the two most active conferences in each topic. Note that the row entitled "Others" includes the total percentage of participation of the other conferences.

5 DISCUSSION

In this section, we have discussed and summarized the main achievements of our review with respect to the research questions specified in Section 3.1.1. In Section 5.1, we have summarized the current state of the art concerning DPs research. In Section 5.2 we have discussed the findings of the demographics of patterns research. Finally, in Section 5.3, we have determined the research emphasis on each topic.

5.1 Research topics on DPs

As mentioned before, the main goal of our study is to provide a taxonomy of the research topics related to DPs. Our results suggest six main topics on DPs research, namely (a) Pattern Development, (b) Pattern Usage, (c) Pattern Mining, (d) Quality Evaluation, (e) Pattern Specification, and (f) Miscellaneous Issues.

Our new research taxonomy, compared to the previous classification scheme in this area (Ampatzoglou et al. 2013), has one additional category titled "Pattern Development". The main reason for this difference is the scope of our study which is all the DPs that exist in the literature, while Ampatzoglou et al. (2013) only considered GoF DPs. The Pattern Development category indicates any development in the field of DPs research, including (a) introducing a new pattern or new pattern language, (b) discussing pattern variants, pattern evolution, composing patterns, or improving a specific pattern, and (c) categorizing existing DPs in various fields and domains. Papers which are included in this category are not limited only to the GoF patterns.

5.2 Demographics of DPs research

As mentioned before, the attention to the subject of DPs is increasing (see Fig. 4). The variation of publications during different years can be measured by a polynomial trend line through the data. As illustrated in Fig. 4, rapid growth is found in the number of publications from 1995 to 2010, and after that, the gradient of the fitted curve tends to zero. It should be noted that for year 2010, a significant deviation is observed from the trend line. The reason behind the remarkable deviation could be attributed to the relatively high number of published papers in QUATIC and PLoP conferences proceedings. In 2010 ten papers were published in proceedings of these two international conferences. Similarly, a considerable number of conference papers in 1998, 2001, and 2007 has had a major effect on the deviation of data from the plotted trend line.

The results of Fig. 8 suggest that most publications come from wealthy countries. Considering the absolute numbers, USA and Canada seem to be the most productive countries. However, smaller affluent countries like Germany and Italy are more productive when the numbers are normalized to population or geographical distribution of the publication. The figure elucidates the considerable investment of developed countries in the field of DPs. On the other hand, it discloses the need for more investment by developing countries in the subject.

Table 16 demonstrates that the most active researcher in the DPs field is Yann-Gaël Guéhéneuc. He is the leader of the Ptidej (The Pattern Trace Identification, Detection, and Enhancement in Java) Team, which seeks to develop theories, methods, and tools, to evaluate and to enhance the quality of object-oriented programs. To achieve this goal, one of the research areas that the Ptidej team is focusing on is DPs. Useful information about the other active researchers in Table 16 is shown in in DPs-SM —Chapter 2 —Tables 2-7.

5.3 Research emphasis on each topic

As mentioned in section 4.1, the most popular topics of DPs research are Pattern Development, Pattern Mining, and Pattern Usage. Some conferences including PLoP, EuroPLoP, and OOPSLA are annually held on the DPs which have a special focus on the Pattern Development domain. This motivates the scholars to attend such credible conferences and as a result, the number of publications in this field is higher than other fields of DPs. In addition, in the Pattern Mining field, the lack of a comprehensive algorithm to detect the patterns with an acceptable accuracy encourages the researchers to improve the present algorithms continuously. Furthermore, as seen in DPs-SM \rightarrow Chapter 3 \rightarrow Table 3-1 there are various domains and technologies in which DPs can be used. Since practical studies are important in all fields of science and technology, the Pattern Usage branch is

no exception and it has also attracted the attention of scholars in the DPs field. These notes are the possible reasons for the higher number of publications in Pattern Development, Pattern Mining, and Pattern Usage branches compared to other fields.

6 THREATS TO VALIDITY

One of the main threats to systematic reviews is the problems that might arise during the search and the selection of the primary studies (problems which threaten the completeness of the included papers set). This threat arises from search and selection process. In this paper, we designed a search strategy which takes advantages of two search methods (manual search and snowballing). We conducted a manual search on the selected search spaces and completed our search by snowballing. So, our search strategy is reliable.

For selecting the primary studies, we designed a process in two phases. For the sake of reliability, two reviewers conducted the selection separately, and disagreements were resolved by decision rules and one other reviewer (see section 3.1.3.2). So, we have reduced the threats which may arise in the selection process (such as biases, misunderstandings, etc.).

After finishing the search process, 36 journals and 53 conferences or workshops were selected as the search spaces to find the primary studies which are in the form of paper. So, it is possible that some articles in other journals or conferences are ignored. For reducing this threat and checking the completeness of the included papers, we applied the search and selection evaluation. Our evaluation test set was generated by a separate team (for removing any biases). After applying the evaluation, 3 new journals and 16 new conferences were added to the search space set. However, as mentioned before, we selected the journals and conferences or workshops under consideration of the defined criteria (see section 3.1.3.1). So, in the current mapping study, a good set of journals and conferences or workshops is considered that can be used to find relevant papers with high quality. Furthermore, we selected "design pattern" term as the search string and searched this term in the title, abstract, and full-text of the papers (for manual search). We assumed that "design pattern" term exists in the full-text of most the papers that deal with DPs and according to the purpose of this study, it is not unexpected.

During the data extraction, some threats such as researcher biases and misunderstandings could appear. To remove these threats from our study, the data extraction forms were traced back and checked by another reviewer.

The other threat to validity is selecting a name for each category. As mentioned in Section 3.3.4, we chose a name for each category according to the most frequent keywords in it and its concept. For example, for the category of Pattern Mining, there were some keywords like "Detection", "Mining", and "Recovery". Nevertheless, we chose "Pattern Mining" as the name of the category because it is more inclusive. However, for some categories, the selected name is not within the keywords of that category. Therefore, it is possible that there was a more appropriate term for naming a category which may be ignored. In these cases, we discussed the selected names (according to the concept and keywords) in our team to remove potential biases.

7 CONCLUSION AND FUTURE WORKS

In this paper, we conducted an SMS on the field of DPs to identify some key issues including: (a) topics and sub-topics, (b) frequency of publications in each topic (c) trends and gaps, (d) active countries, researchers, and venues, and (e) common keywords and phrases. So, a total of 2775 journal and conference papers were identified (during conducting the search process and the evaluation) and 637 papers were included. Then, the data necessary to answer the research questions were extracted, and the included papers were tabulated based on these data.

The results show that the DPs field is an active and attractive research topic and in recent decades, the trend of the publications in this field is increasing. Concerning the geographical distribution of publications, USA and Canada are the most active countries in this field.

The most important contribution of this paper is proposing a classification for the research topics in the field of DPs. As shown in Fig. 6, we presented a taxonomy which includes six classes: 1- Pattern Development, 2-Pattern Usage, 3- Pattern Mining, 4- Quality Evaluation, 5- Pattern Specification, and 6- Miscellaneous Issues.

Pattern Development, Pattern Mining, and Pattern Usage are the most active topics, while Pattern Evaluation and Pattern Specification attract less attention. So, future works should consider these gaps and trends. For example, proposing a systematic review on Pattern Development, Pattern Usage, or Pattern Mining can be a valuable endeavour. Moreover, the deficiency of research with the contribution of proposing a method

for the evaluation or specification of DPs is noticeable and more research is required in these topics. Concerning the active venues, PLoP and Journal of Systems and Software devoted the most publications. According to the results, publishing papers (with the focus on the DPs) in 39 ISI journals and 67 conferences with high quality indicates that DPs are an important and noteworthy field in software engineering.

Table F: Data Extracted for the Evaluation Phase

	Table F: Data Extracted for the Evaluation Phase	
Param.	Papers	Paper
Name		Info*
Yann-Gaël	An empirical study of the relationships between design pattern roles and class change proneness	Existed
Guéhéneuc	Instantiating and detecting design patterns: Putting bits and pieces together	Existed
	Using design patterns and constraints to automate the detection and correction of inter-class design defects	Existed
	Do Design Patterns Impact Software Quality Positively?	Existed
	Evaluating the impact of design pattern and anti-pattern dependencies on changes and faults	Existed
	Mining the relationship between anti-patterns dependencies and fault-proneness	Existed
	Domain matters: bringing further evidence of the relationships among anti-patterns, application domains, and quality-related metrics in java mobile apps	Existed
	A Study on the Relation between Antipatterns and the Cost of Class Unit Testing	Existed
	Ptidej: A flexible reverse engineering tool suite	Existed
	Identification of design motifs with pattern matching algorithms	Existed
	Evaluating the use of design patterns during program comprehension–experimental setting	Existed
	DEQUALITE: building design-based software quality models	Existed
	Design Pattern Application: Pure-Generative Approach vs. Conservative-Generative Approach	Existed
	A Taxonomy and a First Study of Design Pattern Defects	Existed
	Playing roles in design patterns: An empirical descriptive and analytic study	Existed
	DeMIMA: A Multilayered Approach for Design Pattern Identification	Existed
	An exploratory study of the impact of anti-patterns on class change-and fault-proneness	Existed
	From a domain analysis to the specification and detection of code and design smells	Existed
	P-MARt: Pattern-like Micro Architecture Repository	Existed
	Improving design-pattern identification: a new approach and an exploratory study	Existed
	An empirical study on the efficiency of different design pattern representations in UML class diagrams	Existed
	Meta-modeling design patterns: Application to pattern detection and code synthesis	Included
	Using explanations for design-patterns identification	Included
	A domain analysis to specify design defects and generate detection algorithms	Included
	Ptidej: Promoting patterns with patterns	Included

Correction of high-level design defects with refactorings Included		Design patterns: A round-trip	Included

Abbas Rasoolzadegan has received his B.Sc. degree in Software Engineering from Aeronautical University, Tehran, Iran, in 2004. He has also received M.Sc. and Ph.D. degrees in Software Engineering from Amirkabir University of Technology, Tehran, Iran, respectively in 2007 and 2013. He is currently an Assistant Professor with the Computer Engineering Department of Ferdowsi University of Mashhad. His main research focus is on software quality engineering, especially in terms of design patterns and refactoring. For more details see the SQLab homepage: http://sqlab.um.ac.ir.

Bahareh Bafandeh Mayvan is currently Ph.D. candidate in software engineering at Ferdowsi University of Mashhad (FUM). She received her B.Sc. degree in computer engineering from FUM in 2010 and her M.Sc. degree in computer engineering from University of Tehran in 2014. Her current research efforts include software quality engineering, graph theory, design patterns, and image processing.

Zahra Ghavidel Yazdi is master student in software engineering at Ferdowsi University of Mashhad (FUM). She received her B.Sc. degree in Computer Engineering from FUM and she is currently working on software quality engineering at Software Quality Lab (SQL) in FUM.
